

Functional Specification Document – ServiceNow Incident Automation

Implement Client Script & UI Policy (Incident) for NM Project
Date: 03 October 2026 | Team ID: NM-TEAM-ID

1. Introduction

Project Title: Implement Client Script & UI Policy (Incident) for NM Project
Project Type: Naan Mudhalvan ServiceNow Project
Team ID: NM-TEAM-ID

2. Project Overview

Purpose: improve Incident form quality using Client Scripts and UI Policies. The solution guides agents, automates priority calculation, and enforces required information for important Incident states.

3. Functional Scope

Impact/Urgency-based Priority calculation.

Resolved-state mandatory resolution information.

On Hold reason enforcement.

Client-side submission validation.

Functional and UAT testing.

4. Configuration Details

Table: Incident [incident].

Client Script type: onChange for Impact/Urgency priority calculation.

Client Script type: onSubmit for Resolved validation.

UI Policy: State = Resolved.

UI Policy: State = On Hold.

5. Implementation Notes

Use the standard ServiceNow GlideForm API (g_form). Confirm choice values and field names in the target instance because ServiceNow configurations can customize them.

6. Testing

Execute positive, negative, boundary, and regression tests from the UAT document. Capture screenshots for each major rule.

7. Deployment

Validate in development/test first, capture configuration in an Update Set, test after migration, and deploy through the approved NM project process.

8. Known Limitations

Client Scripts and UI Policies are client-side controls. They should not be treated as the sole security boundary; ACLs and server-side rules remain authoritative for access and data integrity.

9. Future Enhancements

Add server-side validation where required, automated ATF tests, additional state-specific rules, role-based UI behavior, and reporting on incomplete incidents.
